Abstract. We present the current version of STRIDER[1], a versatile system for the disambiguation of structure-based information like XML schemas, structures of XML documents and web directories. It can be of support to the semantic-awareness of a wide range of applications, thanks to its novel and fully-automated disambiguation algorithms.

1 Introduction

Knowledge based approaches are rapidly acquiring more and more importance in a wide range of application contexts, like schema matching and query rewriting [2, 5], peer data management systems (PDMS), XML data clustering and classification [8] and ontology-based annotation of web pages and query expansion [1, 3]. In these contexts, most of the proposed approaches share a common basis: They focus on the structural properties of the accessed information, which are represented adopting XML or ontology based data models, and their effectiveness is heavily dependent on knowing the right meaning of the employed terminology. Fig. 1-a shows the hierarchical representation of a portion of the web directories offered by Google™. It is an example of a typical tree-like structure-based information managed in the above mentioned contexts and which our approach is successfully able to disambiguate. It contains many polysemous words, from `track` to which WordNet [6], the most used commonly available vocabulary, associates 11 meanings, to `home` (9 meanings), `intelligence` (5 meanings), and so on. The information given by the surrounding nodes allows us to state, for instance, that `track` is a "racing course" and not a "selection of music", and `intelligence` is "a unit responsible for gathering information about an enemy" and not "the ability to comprehend".

In this paper we demonstrate the current version of STRIDER, a system which can be of support to these kinds of approaches in overcoming the ambiguity of natural language, as it makes explicit the meanings of the words employed in tree-like structures. STRIDER builds on the novel versatile structural disambiguation approach we proposed in [4].

* A previous version of this demo has been presented at the EDBT'06 Conference. This work is partially supported by the FIRB NeP4B national project.

2 An overview of the STRIDER System

STRIDER is designed to perform effective disambiguation of tree-like structures. As shown in Fig. 1-b, which depicts the complete architecture of our system, STRIDER takes in input structure-based information like XML schemas, structures of XML documents and web directories and disambiguates the terms contained in each node's label using WordNet as external knowledge source. The outcome of the disambiguation process is a ranking of the plausible senses for each term. In this way, the system is able to support both the completely automatic semantic annotation whenever the top sense of the ranking is selected and the assisted one through a GUI that assists the user providing useful suggestions. The STRIDER system has the following features:

- automated extraction of terms from the schema nodes (**Terms and Senses Extraction** component in Fig.1-b);
- high-quality and *fully-automated disambiguation* that: (i) is independent from training or additional data, which are not always available [7]; (ii) exploits a context which goes beyond the simple "bag of words" approach and preserves the information given by the hierarchy (*graph context*); (iii) allows flexible extraction and full exploitation of the graph context according to the application needs (**Graph Context Extraction** component in Fig.1-b); (iv) enriches the graph context by considering the *expanded context*, with additional information extracted from WordNet definitions and usage examples (**Expanded Context Extraction** component in Fig.1-b);
- *interactive and automated feedback* to increase the quality of the disambiguation results;
- user-friendly GUI speeding up the *assisted disambiguation* of schemas, providing an easy-to-use layout of the informative components.

Technical details about the implemented techniques for structural disambiguation are available in [4].

3 Demonstration

In this section we demonstrate the main features of STRIDER. The effectiveness of the system has been experimentally measured on several tree-like schemas differing in the level of specificity and polysemy [4] (schemas are available online at `www.isgroup.unimo.it/paper/strider`).

Fig. 2 shows STRIDER's GUI with the results of the disambiguation process for the Google example (Fig. 1-a). In the left part of the GUI we see columns `Node`, `Term` that show the outcome of the automated extraction of terms from the tree's nodes and column `Synset` that contains the chosen sense for the corresponding term. For flexibility purposes, the GUI allows users to fill it in either by manually choosing one of the senses in the right part or by pressing the *Magic Wand* button. This simple act triggers the fully *automatic disambiguation* process of STRIDER which is applied to the entire loaded tree and automatically chooses the top sense in the ranking of each term. When the user highlights a term in the left part of the GUI, the right part shows all the available senses and for each of them the synset's hypernym hyerarchy. One of the major strengths of our system is the versatility of being able to choose the crossing setting that is best suited to the tree characteristics. For instance, when the crossing setting is made up of the whole tree, the term `bulb` of Fig.1-a is not disambiguated as "an underground stem serving as a reproductive structure", but as "an electric lamp" due to the presence of terms like `plant` that could have the meaning of "industrial complex" rather than "vegetables living organism". This behavior is typical of trees that gather very heterogeneous concepts like web directories. On the other hand, only by using the whole tree as the crossing setting in trees that have a very particular scope, for instance the SIGMOD Record scientific digital library, terms like `conference` and `issue` are correctly disambiguated whereas

a restricted crossing setting made of only ancestors and descendants provides wrong results. In general, the performed tests demonstrate that most of the term's senses are correctly assigned straightforwardly with the disambiguation (the mean precision level on the tested trees is generally over 80% [4]). Such good performance is obtained even when the graph context provides too little information, as in generic bibliographic schemas, thanks to the *context expansion* feature which is able to deliver a higher disambiguation precision, by expanding the context with additional related nouns contained in the description and in the examples of each sense in WordNet. To get even better results the user could choose to refine them by performing successive disambiguation runs; for this purpose he/she is able to deactivate/activate the influence of the different senses of the available context words on the disambiguation process. Further, the flexibility of our approach allows the user to benefit from a completely *automated feedback*, where the results of the first run are refined by automatically disabling the contributions of all but the top ranked X senses in the following runs.

4 Conclusions

The disambiguation performances achieved by STRIDER are encouraging and demonstrate the very good effectiveness of the adopted approach. The intuitive GUI provides easy interaction with the user. Further, the system is currently undergoing a major feature enhancement and, in order to meet the needs of the most cutting edge semantic-aware applications even better, it will soon be able to: (a) support the disambiguation of several additional input formats, such as complete relational schemas and non tree-like ontologies; (b) exploit additional disambiguation techniques offering integration with a larger number of external knowledge sources, including on-line search engines and thesauri.
